SpendWise — Deployment and Submission

AWS SAM, Cognito, Amplify, GitHub, environment configuration and final verification

What this document controls

Use after the project passes local checks. It guides Antigravity to provide exact commands and a verifiable deployment checklist rather than inventing URLs or claiming unperformed work.

COPY THE FULL PROMPT BELOW INTO ANTIGRAVITY

Use this prompt as one message. Let Antigravity inspect the repository, make the requested changes, run checks, and report what it actually completed. Do not skip the checkpoints.

Prepare SpendWise for a real assessment deployment using Next.js and AWS serverless services only. EC2 is prohibited.

```
BEFORE DEPLOYING
- Inspect repository and current build status.
- Verify frontend production build and backend SAM template.
- Identify all environment variables and distinguish public configuration from secrets.
- Confirm no secrets are committed and `.gitignore` excludes `.env*` except `.env.example`, build output and dependencies.
- List the resources the SAM template will create and warn about possible charges.
- Do not run destructive cleanup commands without asking me first.

BACKEND DEPLOYMENT
Provide beginner-friendly ordered commands for:
1. AWS CLI identity verification.
2. `sam validate --lint`.
3. `sam build`.
4. `sam deploy --guided`.
5. Choosing an appropriate region and stack name.
6. Reviewing IAM capabilities and resource changes before approval.
7. Retrieving the actual API endpoint from stack outputs.
8. Configuring Cognito, CORS and any required environment parameters.
9. Testing health, authenticated API calls and authorization.
Do not invent output values or endpoints. Explain any step requiring the AWS Console.

FRONTEND DEPLOYMENT
- Use AWS Amplify Hosting connected to the actual Git repository.
- Detect the frontend root directory and package manager.
- Provide correct build settings for the actual project structure.
- Configure NEXT_PUBLIC_API_BASE_URL and public Cognito configuration.
- Explain that changing environment variables usually requires a new build/deployment.
- Ensure production CORS allows the actual Amplify origin and API uses HTTPS.
- Do not publish a URL until Amplify reports a successful deployment.

FINAL VERIFICATION
- Sign in as a test user.
- Create a transaction and confirm it remains after refresh.
- Verify budgets and analytics.
- Test cross-user access with a second account if possible.
- Verify receipt uploads only if implemented.
- Test on mobile and desktop.
- Review CloudWatch logs for errors without logging sensitive details.

DOCUMENTATION
Create a professional root README with:
- Project summary and screenshots only if available.
- Features and known limitations.
- Architecture diagram in Mermaid.
- Stack and folder structure.
- Prerequisites and local setup.
- Environment variables.
- Cognito configuration and security model.
- API endpoint documentation.
- SAM backend deployment and Amplify frontend deployment.
- Tests run and how to reproduce them.
- Cost-awareness and cleanup guidance.

OUTPUT
Give me exact commands in execution order and say which directory to run them from. Never claim deployment succeeded unless v
```
